(57) **ABSTRACT**

During an interaction with a web page, user interface events are recorded and augmented with page layout data from the document object model. An event stream is formed with the page layout data and communicated to an event server. The event server processes the event stream to determine a location at which the events were generated, which can be used to predict an area of a user's attention.

# SYSTEM, METHOD AND COMPUTER READABLE MEDIUM FOR DETERMINING USER ATTENTION AREA FROM USER INTERFACE EVENTS

## FIELD OF THE INVENTION

This disclosure relates to a system, method and computer readable medium for processing of user interface events.

## BACKGROUND OF THE INVENTION

In many web based applications, it may be beneficial to determine where the attention of a user is focused during an interaction. One existing solution is to use click stream data, it being considered that a user's attention is directed towards the location of the click. However, click stream data is typically course grained and there can be relatively long periods of time between complete mouse click events in which the focus of the user's attention is unknown.

What is required is a system, method and computer readable medium for better determining a locus of attention of a user.

## SUMMARY OF THE INVENTION

In one aspect of the disclosure, there is provided a method for predicting an area of focus of a user during an interaction with a web page. The method comprises recording at least one document object model element within a web browser, recording a plurality of user interface events in respect of the at least one element of the document object model, and processing the plurality of user interface events to predict an area of focus of the user.

In one aspect of the disclosure, there is provided a web server configured to generate a web page and provide the web page to a client browser. The web page comprises web page content visible to a user, an event observer module that records user events generated in respect of the webpage content and communicates event stream data to an event server and a layout module that augments the event stream data with page layout data.

In one aspect of the disclosure, there is provided a computer-readable medium comprising computer-executable instructions for execution by a processor, that, when executed, cause the processor to receive an event stream comprising a plurality of events generated during a user interaction with a web page, and process the event stream to determine an area of focus of a user during the user interaction with the web page.

## BRIEF DESCRIPTION OF THE DRAWINGS

The invention will now be described, by way of example only, with reference to specific embodiments and to the accompanying drawings in which:

FIG. 1 illustrates a system for determining a user's attention area during a web page interaction;

FIG. 2 illustrates a method for predicting a user's focus area;

FIG. 3 illustrates an example of an event header message;

FIG. 4 illustrates an example of an event stream message;

FIG. 5 illustrates an operation of a layout module;

FIG. 6 illustrates an operation of an attention analysis module;

FIG. 7 illustrates an attention analysis request and response;

2

FIG. 8 illustrates an operation of a service provider module;

FIG. 9 illustrates a processor and memory of an event server;

FIG. 10 illustrates an instruction set that may be executed on the processor and memory of FIG. 9; and

FIG. 11 illustrates the processor and memory of FIG. 9 in association with a processor and memory of a web server.

## DETAILED DESCRIPTION OF THE INVENTION

A system in accordance with an embodiment of the disclosure is depicted in FIG. 1. In the system 10, a client 18 provides web page requests 13 to a web server 14, in response to which, the web server 14 provides page content 11 for display in a browser 15 of the client 18. Typically, the web page 11 will include visible content 27.

In typical webpage protocols, a document object model (DOM) of a webpage structure may include a document, a body and several elements, including elements embedded within each other. A DOM is an example of a hierarchically structured document. Events, in particular user triggered events such as mouse movements, cursor movements, mouse clicks or keyboard events may be generated at various locations on the page. Application code running in the webpage environment may register event handlers on various web page objects. The event handlers may handle events in a variety of ways. A first event handling method is referred to as event capturing. Event capturing provides an event first to the top most object in the web page hierarchical structure, i.e. DOM, and onward in a descending fashion as follows:

DOCUMENT→BODY→ELEMENT→A→ELEMENT

Event bubbling provides an event first to the bottom most object and onward in an ascending fashion as follows:

ELEMENT B→ELEMENT→BODY→DOCUMENT

During an interaction between a user at the client and the web page, it may become desirable to determine a locus of attention of the user. One reason for determining where the user's attention is focused is for the placement of additional content such as advertising or other graphics, text, images, videos etc that are intended to capture the user's attention. A method for predicting an area of focus of a user during an interaction with a web page is illustrated in FIG. 2. At step 101, the structure of the web page DOM is recorded including one or more elements of the DOM. A plurality of user interface events are recorded in respect of the elements of the DOM 102. The events may be mouse moves, partial clicks (i.e. either mouse down or mouse up), text entries, etc. The recorded user interface events are then processed 103 to predict an area of focus of the user.

In accordance with an embodiment of the invention, the web server 14 is modified such that the web page content provided to the client 18 includes an event observer module 26 and layout module 24, both of which may be provided as appropriate code or scripts that run in the background of the client's browser 15. In one embodiment, code for providing the event observer module 26 and the layout module 24 is provided to the web server 14 by a third party service, such as provided from an event server 12, described in greater detail below.

The event observer module 26 and the layout module 24 may be provided as code embedded in a web page 11 from the web server 14. Alternatively or in addition, the event observer module 26 and the layout module 24 may be

provided as a link back to the web server **14** or a third party server, e.g. event server **12**, for the resource containing the code which the web browser will fetch as part of loading the web page.

The event observer module **26** observes events generated in a user interaction with the web page **11** at the client **18**. The event observer module **26** records events generated within the web browser **15**, such as mouse clicks, mouse moves, text entries etc., and generates event streams **21** including an event header message **22** and one or more event stream messages **23**. It will be apparent to a person skilled in the art that terms used to describe mouse movements are to be considered broadly and to encompass all such cursor manipulation devices and will include a plug-in mouse, on board mouse, touch pad, eye-tracker, etc.

The event observer module **26** provides the event streams **21** to the event server **12**. The event server **12** includes an event module **25**, an attention analysis module **39** and a suitable data store **28**, which though shown in FIG. **1** within the event server **12**, may also be provided as an offsite data store. The event server **12** also includes a service provider module **17** which interfaces with a processing module **19** of the web server **14**.

An example of an event header message **30** is illustrated in FIG. **3** and an example of an event stream message **40** is illustrated in FIG. **4**. The messages **30**, **40** show a number of components that can be included, though in various embodiments, not all of these components may be required and additional components may be added. Primarily, an Interaction\_ID **32**, **42** uniquely identifies an interaction between the client **18** and the web server **14** and aids to identify the particular event stream **21**. The event header message **30** and the event stream message **40** may also identify the Uniform Resource Locator (URL) **31**, **41**. Fixed parameters such as the operating system **33** and browser type **34** may form part of the event header message **30**. Screen parameters **36**, **46** such as the screen size, depth and orientation may be included in either or both of the event header message **30** or the event stream message **40**. A capture event stream **43** and a bubble event stream **44** specifies the events recorded in respective event capture and bubbling phases during the web page interaction. Each event may be indicated by the event type, time and x/y location relative to the viewport. Not all web browser types support event capture, and thus the capture event stream **43** may be empty. Where required, events missing from the event bubble stream may be inferred, for example as described in the Applicant's co-pending application Attorney Docket No. HAUSER002, the entire contents of which are explicitly incorporated herein by reference. An event\_count field **45** may indicate the total number of unique events observed by the event observer module including those events not included in the event stream message **40** due to a current sampling function excluding them. Timing parameters **48** may indicate the relevant period over which the event stream message **40** is current.

The event observer module **26** passes the event streams **21** to the event module **25** of the event server **12**. In the embodiment illustrated in FIG. **1**, the event streams **21** are provided directly to the event module **25**. However, the event streams **21** may also be provided indirectly, e.g. via the web server **14**.

The layout module **24** processes the web page content on the client browser **15** and augments the event stream messages **21** with viewport and DOM element layout information. Additional fields of the event stream messages **40** shown in FIG. **4** include a viewport location **81**, DOM

element location changes **82** and DOM structure changes **83**. The DOM element location changes **82** and DOM structure changes **83** may be reported in absolute terms, or may be reported as changes in these parameters since the last report. The viewport location **81** may include a time interval over which the viewport location information can be considered valid.

During an interaction with the web page **11**, a user navigates the web page **11** and may enter content where appropriate, such as in the HTML form elements. During this interaction events are generated and recorded by the event observer module **26**. Events may include mouse clicks, mouse moves, key strokes etc. Periodically, the event observer module **26** formulates an event stream message **23**, at which time, the event module provides a callback to the layout module **24** for layout data to be included in the event stream message.

A process **200** performed by the layout module **24** in response to the callback is shown in FIG. **5**. The layout module **24** receives the event observer module callback at step **201** and proceeds to compare a current DOM structure of the web page **11** with the last reported DOM structure **202**. The layout module **24** may register itself to watch DOM changes or may simply enumerate the structure as needed. If changes are observed, then a DOM structure summary is provided to the event observer module **26** to be added to the event stream message **23** (step **203**). At step **204**, the DOM element layout size is compared to the last reported layout size for each DOM element. New elements and any changes of the DOM element layout sizes are communicated **205** to the event observer module **26** for inclusion in the event stream message **23**. The DOM element layout size can be computed using element properties "offset left" and "offset top" as is known. Alternatively, the events generated by the user, e.g. mousemove etc., can be correlated to the first element to see the event in the event bubbling phase. Since the events have x,y coordinate positions, the action of moving the mouse across a DOM element rendered in the viewport window will allow local recording of the size and location of the respective DOM element. At step **206**, the viewport location history is communicated to the event observer module **26** for inclusion in the event stream message **23**, after which the event stream message **23** may be communicated to the event server **12**.

The event server **12** receives the event stream **21** including the augmented event stream messages **23** and processes the event streams in an event module **25**. Events may be extracted from the event stream messages **23** together with the viewport data and communicated to the attention analysis module **39** for additional processing. If the event stream **21** includes a new InteractionID, data storage may be allocated in the data store and an initial DOM structure and element layout information may be recorded. When additional event stream messages are received, any updates to the viewport location, DOM structure and DOM element layout are also stored.

An operation **300** of the attention analysis module is shown in FIG. **6**. At step **301**, the attention analysis module **39** receives an analysis trigger, which might be a request, described in further detail below, or a timeout. The attention analysis module then analyzes the location of the events in the event stream messages relative to the DOM element location in the viewport in order to compute a probabilistic locus of attention for the user (step **302**). In one embodiment, only the most recent event stream message may be analyzed, as this will include the most up to date information of the user's attention area. In one embodiment, the attention

5

analysis module 39 computes the locus of attention from a plurality of mouse move events as these events can provide a fine grained indication of the user's focus in between mouse clicks. The locus of attention may be computed and stored as the user attention time per DOM element. In addition, the attention analysis module 39 may compute user interest events (step 303) such as hints, lingers, hovers, partial clicks, cancelled clicks, "on element exits" etc, any of which may assist in determining where a user's attention is directed. For example, a mousedown event followed by a mousemove may not register as a complete mouseclick, in particular if the mouseup event occurs off of a particular web page element. However, the mousedown, mousemove and mouseup events together may indicate a region of the user's interest or attention focus. In a further example, a mouse move followed by a brief period of time before the next mouse move may indicate a hover over a region of interest to the user.

By way of example, an event stream data excerpt of mousemove events, perhaps arriving in multiple event stream messages, may contain the following events in which the format is [x-position, y-position, time, DOM\_element]: [100, 100, 0, div] [102, 101, 5, div] [104, 100, 10, div] [106, 99, 15, body] [110, 106, 18, div] [119, 115, 20, div] [121, 117, 28, span] [123, 115, 38, div] [126, 112, 45, div] [131, 108, 50, div] [135, 105, 55, div] [138, 99, 60, body] [140, 101, 65, div] [142, 102, 70, div]. The attention analysis of these events may result in a "linger" of the user's attention from time 0 to 70 on the <div> element's content. Analysis may also determine a "hint" of the user's attention from time 15 to 50 toward the <span> element with 20% probability with 80% probability that this hint is toward the <a id="link1"> element which is located below the <span> element. A key to the "hint" analysis is the increased rate of mouse movement (shorter time and more distance) along with the "v" shape of this segment of the mouse track. Note that an attention event, e.g. the "hint", may indicate the locus of attention of the user is on a DOM element that did not receive any client side user interface events (e.g. the <a id="link1"> element did not show up in our mousemove track).

The attention time and the user interest events may be computed for any DOM element or for DOM elements that have a particular identifier attribute within the page. This allows a web page designer to specify content areas for which to monitor user interest.

The attention analysis may be reported to the web server 14 automatically or in response to a request. With reference to FIG. 1, a request message 50 may be sent from a user interest processing module 19 of the web server 14 to the service provider module 17 of the event server 12. The request may be generated during the web page interaction with the client 18, for example at a time when an ad placement is required. A sample request 50 is shown in FIG. 7. The request includes a Request ID 51 and specifies an InteractionID 52 that identifies the interaction between the web server 14 and the client 18. The request 50 also specifies a Boolean value 53 as to whether interest events are to be included in the response. A response message 56 is also shown in FIG. 7. The response message indicates the same Request ID 51 as well as an attention time per DOM element 57. If the Boolean value of the request 53 was set to True, the response 56 will also include an interest events per DOM element value 58, which, in one embodiment, may comprise a list of DOM elements each having a sublist of interest event types and a counter which indicates the mid level interest events analyzed from the event stream such as hints,

6

lingers, hovers, partial clicks, cancelled clicks and/or "on element" exits. The response message 56 can also include an "interaction complete" value 59 which is a Boolean value set to true if the event server 12 considers that the interaction pertaining to the InteractionID is complete, for example if no event stream message has been received by the event server 12 for a particular time, or if an event indicates that the web page has been closed.

A process 400 of the service provider module 17 is depicted in FIG. 8. At step 401, the service provider module 17 receives the request 50 from the user interest processing module 19 of the web server 14. The service provider module 17 then extracts the InteractionID 52 from the request and looks up the InteractionID in the data store 28 (step 402). The attention time per DOM element is then retrieved or computed if new data has arrived or the value is not otherwise available (step 403). Based on the event stream data excerpt described above, the attention time could be as follows (format is a list of [element, time-on-element]): [[<div>, 52], [<body>, 9], [<span>, 9], [<a id="link1">, 0]]. The user's attention was analyzed based on the amount of time interface events were received on DOM elements (time from 0 to 70 has been assigned to DOM elements). If interest events have been requested, then these values can be retrieved from the InteractionID record in the data store 28 or otherwise computed (step 404). Analysis of the current example could result in the interest events as follows (format is a list of [element, interest-event-type, time-interval, probability]): [[<div>, linger, (0,70), 1.0], [<span>, hint, (15,50), 0.2], [<a id="link1">, hint, (15,50), 0.8]]. At step 405, a response message 56 is generated and provided from the service provider module 17 to the user interest processing module 19.

In an alternative embodiment, the event module 25 and attention analysis module 39 may be provided as components of the web server 14, such that all processing of the event streams, including determining the user's focus area, occurs within the web server 14.

In one embodiment, the event server 12 may include a processor 61 operatively associated with a memory 62 as shown in FIG. 9. The memory 62 may store instructions that are executable on the processor 61. In addition, the memory 62 may provide elements of the data store 28. An instruction set 500 that may be executed on the event server processor 61 is depicted in the flowchart of FIG. 10. Specifically, when executed, the instruction set 500 allows the processor to receive an event stream 501 from a web page interaction and process the event stream to determine an area of focus of a user during the interaction with the web page 502.

The analysis of the event stream may be performed in response to a request received from a second processor, such as processor 71 of a web server shown in FIG. 11, that may also be operatively associated with a memory 72. The second processor 71 may provide the interaction identifier through a suitable communications link 65 in a service request, such as the request 50 described above.

An advantage of the embodiments described above includes that the event data provides fine grained attention tracking which is hard to falsify by automated means.

Although embodiments of the present invention have been illustrated in the accompanied drawings and described in the foregoing description, it will be understood that the invention is not limited to the embodiments disclosed, but is capable of numerous rearrangements, modifications, and substitutions without departing from the spirit of the invention as set forth and defined by the following claims. For example, the capabilities of the invention can be performed

7

fully and/or partially by one or more of the blocks, modules, processors or memories. Also, these capabilities may be performed in the current manner or in a distributed manner and on, or via, any device able to provide and/or receive information. Further, although depicted in a particular manner, various modules or blocks may be repositioned without departing from the scope of the current invention. Still further, although depicted in a particular manner, a greater or lesser number of modules and connections can be utilized with the present invention in order to accomplish the present invention, to provide additional known features to the present invention, and/or to make the present invention more efficient. Also, the information sent between various modules can be sent between the modules via at least one of a data network, the Internet, an Internet Protocol network, a wireless source, and a wired source and via plurality of protocols.

What is claimed is:

1. A method for predicting an area of focus of a user during an interaction with a web page, the method comprising:

recording at least one document object model element within a client web browser;

recording, in the client web browser, a plurality of user interface events and recording at least one document object model element in which the respective user interface event occurred;

generating, in the client web browser, at least one event stream message comprising an interaction identifier, the plurality of recorded user interface events and the recorded at least one document object model element; transmitting the at least one event stream message from the client web browser to an event server;

receiving an attention analysis request in the event server, the attention analysis request indicating the interaction identifier; and

in response to receiving the attention analysis request, processing the plurality of user interface events from the at least one event stream message associated with the interaction identifier at the event server to predict an area of focus of the user;

wherein processing the plurality of user events comprises determining an attention time of a user per document object model element and wherein a result of the processing specifies at least one document object model element and the time spent on the respective document object model element.

2. The method according to claim 1 comprising generating a response to the request, wherein the response comprises an indication of an area of focus of the user.

3. The method according to claim 1 wherein processing the plurality of user interface events comprises processing a plurality of mouse move events.

4. The method according to claim 1 wherein processing the plurality of user events comprises determining at least one user interest event selected from a hint, linger, hover, partial click, cancelled click or on element exit.

5. A system comprising:

an event server;

a web server configured to:

generate a web page comprising:

web page content visible to a user;

an event observer module that, when executed in a client browser, records an interaction identifier and user events generated in respect of the webpage content and communicates event stream data comprising the user events and the interaction identifier from the client

8

browser to the event server, the user events comprising an indicator of an element of a Document Object Model of the web page; and

a layout module that augments the event stream data with page layout data; and

provide the web page to the client browser;

wherein the event server is configured to receive an attention analysis request from the web server comprising the interaction identifier and in response to receiving the attention analysis request, process the plurality of user events from the event stream data pertaining to the interaction identifier to predict an area of focus of the user; and

wherein the event server is configured to generate a list of attention time per Document Object Model element of the web page and wherein a result of the processing by the event server specifies at least one document object model element and the time spent on the respective document object model element.

6. The system according to claim 5 wherein the layout module is generated to augment the event stream data with data relating to one or more elements of a document object model of the web page.

7. The system according to claim 6 wherein the layout module is generated to augment the event stream data with data relating to at least one of document object model location changes and document object model structure changes.

8. The system according to claim 5 wherein the event observer module is generated to generate at least one event stream message comprising a plurality of events and a viewport location of each of the plurality of events.

9. The system according to claim 5 wherein the event observer module is generated to record a plurality of mouse move events.

10. The system according to claim 5 comprising the event server, wherein the event server is configured to process the plurality of user events to predict an area of focus of the user.

11. A non-transitory computer-readable medium comprising computer-executable instructions for execution by a processor, that, when executed, cause the processor to:

receive an event stream from a client browser, the event stream comprising an interaction identifier and a plurality of events generated in the client browser during a user interaction with a web page, the events comprising an indicator of an element of a Document Object Model of the web page;

receiving an attention analysis request in the event server, the attention analysis request indicating the interaction identifier; and

in response to receiving the attention analysis request, retrieve user attention analysis data in respect of the interaction identifier; and

process the retrieved user attention analysis data to determine an attention time of a user per document object model element of the webpage and

process the event stream to determine, using the attention time of a user per document object model element of the webpage, an area of focus of a user during the user interaction with the web page, wherein a result of the processing specifies at least one document object model element and the time spent on the respective document object model element.

12. The non-transitory computer-readable medium according to claim 11 comprising instructions, that when

executed by the processor, cause the processor to determine an area of focus of a user from a plurality of mouse move events.
